Compute contrasts or linear functions of least-squares means, and comparisons of slopes. Plots and compact letter displays.

Package 'lsmeans' - R

Calculates Least Squares Means and Confidence Intervals for the factors of a fixed part of mixed effects model of lmer object. Produces a data frame which resembles to what SAS software gives in proc mixed statement. The approximation of degrees of freedom is Satterthwate's. This is a deprecated function, use lsmeansLT function instead.

R scripts that use lsmeans will still work with emmeans after making minor changes (use emmeans::convert_scripts ()). Existing objects created with lsmeans can be converted to work with the new package via emmeans::convert_workspace (). See vignette ("transition-from-lsmeans", "emmeans") for more details.

Typically you should ignore the values of the LS means themselves (lsmeans) when using them with clm and clmm models. With default settings, the values of the LS means and the values of differences among the LS means are not easy to interpret.

For categorical variables, it is possible to calculate least squares means, also known as population marginal means or adjusted means . These can be thought of as the means for a hypothetical population with a certain distribution of the predictor variables. In the simplest case, with a single categorical predictor, the least squares means are simply the observed sample means for the categories.

This is easy to do using lsmeans: lsmeans(logmixed_ranks[[i]], pairwise ~ rating_ranks | indicator_var, adjust = "tukey") or. lsmeans(logmixed_ranks[[i]], pairwise ~ indicator_var | rating_ranks, adjust = "tukey") By the way, if you use adjust = "mvt", you will obtain exactly the same adjustments that ght uses for its single-step procedure.
